Generative AI: Requirements

Submit a RAG (Retrieval-Augmented Generation) chatbot or app that anyone can open and use online, plus a demo video and the full source code.

1. Deployed RAG chatbot/app

1. Deploy the app to a public hosting platform (for example Vercel, Streamlit Community Cloud, Hugging Face Spaces, Render or similar). A localhost link is not accepted.
2. The app must open without logging in and without installing anything.
3. The app must demonstrate the full RAG pipeline: your own document/knowledge source is ingested, chunked, embedded and stored; a user question retrieves relevant chunks; the model answers using those chunks.
4. Answers should be grounded in your documents. Show the sources or passages used wherever possible, and handle questions the documents cannot answer without making things up.
5. Keep the app running until grades are released. Store API keys as environment variables or secrets, never inside the code or repository.
6. Add a short note on the app page or in the README about any usage limit (for example free-tier API quota) so the teacher knows what to expect.

2. Demo video

1. Record a screen demonstration of your RAG output. Recommended length: 5 to 8 minutes.
2. Cover, in order: the problem and the knowledge source you used; the architecture (embedding model, vector store, LLM, framework); a live walkthrough of the deployed app; at least 3 sample questions, including one the documents cannot answer; and what you would improve.
3. Upload the video to Google Drive or YouTube (unlisted is fine).
4. Set sharing to **Anyone with the link** (Viewer). In Google Drive: right-click the video, choose Share, change General access to Anyone with the link.
5. Open the link in an incognito window to confirm it plays before you submit.

3. Public GitHub repository

1. Push your complete project to a GitHub repository and set its visibility to **Public** (Settings, then Danger Zone, then Change visibility).
2. The repository must include the source code, a requirements or package file, and a README.
3. The README must state: project title and purpose; the live app link; the tech stack; how to run it locally; how the RAG pipeline works; and where the sample documents came from.
4. Include a `.env.example` listing the variable names needed (without real keys). Never commit real API keys. If a key was exposed, revoke it and create a new one.
5. Submit the repository URL in the Google Classroom submission bin together with the live app link and the video link.

Generative AI: Grading Criteria (100 points)

Criterion	Points	Full marks when
Public deployment	20	The app opens from a public link with no login, loads reliably and is usable by anyone
RAG implementation	25	Documents are ingested, chunked, embedded and retrieved correctly; answers are grounded in the retrieved content and cite their sources
Application quality and usefulness	15	The app solves a clear, realistic problem; the interface is clean and easy to use; errors and out-of-scope questions are handled sensibly
Demo video	20	Video is accessible to anyone with the link, covers every required part in the guide above, is clear and well paced, and shows the live deployed app
GitHub repository	15	Repository is public, organised, has a complete README, setup steps and `.env.example`, and contains no exposed secrets
Completeness and timeliness	5	All three links are submitted together in the Classroom bin on or before the deadline

Automatic deductions

- Link requires sign-in or access request: up to 10 points off per item, until fixed.
- App runs only on localhost or is not working: Public deployment scores 0.
- API keys committed to the repository: 5 points off.
- Work copied from another student or from a tutorial without clear changes and credit: referred for academic dishonesty.
